The preparation of dibenzocycloheptyne- $\text{Co}_2(\text{CO})_6$ complexes by intramolecular Nicholas reactions of biaryl-2-propargyl alcohol- $\text{Co}_2(\text{CO})_6$ derivatives is described. Reductive decomplexation of the dibenzocycloheptyne- $\text{Co}_2(\text{CO})_6$ complexes affords the corresponding dibenzocycloheptenes, individual members of which have been employed in a formal total synthesis of (-)-allocolchicine, the preparation of 6,7-dihydro-3,4,9,10,11-pentamethoxy-5H-dibenzo[a,c]cyclohepten-5-one, and the enantioselective total syntheses of NSC 51046 and its 3,8,9,10-tetramethoxy regioisomer.

Introduction

The allocolchicines are a group of compounds containing a tricyclic 6,7,6-system with a highly oxygen substituted A ring. Individual members of this group, including (-)-allocolchicine (**1**), N-acetylcolchicinol methyl ether (NSC 51046, **2**), N-acetylcolchicinol (**3**) and its dihydrogenphosphate (ZD 6126, **4**) have gained considerable attention by virtue of having been found to be active against a number of cancer cell lines.¹ These act by inhibiting tubulin assembly and polymerization, therefore arresting cell mitosis. A number of additional naturally occurring allocolchicines, including (-)-androbiphenylene (**4**), (-)-colchibiphenylene (**5**), (-)-jerusalemine (**6**), (-)-salimine (**7**), and (-)-suhailamine have also been isolated;² the latter two of these have undergone structural revision or are structurally in question.³

Figure 1. Common allocolchicines.

Synthetic access to the allocolchicines historically has been based on oxidation of colchicine itself,⁴ although racemic syntheses or those involving resolution are known.^{3,5} More recently, the activity of these compounds has stimulated an interest in the enantioselective synthesis of allocolchicines. Initiated by Wulff's Diels-Alder based synthesis of (-)-allocolchicine itself,⁶ members of this class of compounds have seen synthesis by way of enyne metathesis/Diels-Alder reactions ((-)-N-acetylcolchicine analogs),⁷ oxidative coupling and copper mediated cross coupling ((-)-N-acetylallocolchicinol),⁸ C-H activation reactions ((-)-allocolchicine formal synthesis),⁹ and aldol condensation chemistry ((-)-N-acetylallocolchicinol).^{8b,10} In addition, a recent siloxane coupling/ring expansion reaction chemistry approach to (±)-NSC 51046 has been reported.¹¹

The application of alkyne-Co₂(CO)₆ complexes in the synthesis of seven- membered ring compounds has been demonstrated by our group¹² and by other groups,¹³ most often based on Nicholas

reaction chemistry. The reactions are suited to seven membered ring synthesis due to fact that complexation of alkynes to $\text{Co}_2(\text{CO})_6$ induces a change in bond angle to ca. 140° ,¹⁴ in that $\text{S}_{\text{N}}1'$ reactivity on the cationic propargyldicobalt complex to give a 5- membered ring system does not occur, and since the electrophilicity of these cations is such that arenes substituted with electron donating groups are sufficiently nucleophilic for facile reaction.¹⁵ In particular, given the propensity of propargyldicobalt cations for reaction with electron rich arenes and the demonstrated ability of (Z)-arylalkene substituted propargyl acetate complexes to react to form benzocycloheptyne- $\text{Co}_2(\text{CO})_6$ complexes,^{12d} we considered the potential applicability of intramolecular Nicholas reaction chemistry to dibenzocycloheptanes and consequently allocolchicines to be highly promising. We have reported on the viability of this approach in preliminary form, and now describe this chemistry in complete fashion.¹⁶

Results and Discussion

The general outline of the access to the 6-7-6 system was envisioned to occur by construction of the $\text{Co}_2(\text{CO})_6$ complexes of biaryl-2-propargyl alcohol derivatives (**8**), which would deliver dibenzocycloheptyne- $\text{Co}_2(\text{CO})_6$ complexes (**9**) in the presence of a Lewis acid. The former were prepared in most instances by Suzuki-Miyaura coupling reactions of arylboronic acids (**10**) with bromobenzaldehydes (**11**) according the conditions employed by Fürstner,¹⁷ giving biaryl-2-carboxaldehydes (**12a-f**) in good yield (Scheme 1, Table 1). These aldehydes were subjected to the Corey-Fuchs protocol, with trapping of the resulting acetylide by paraformaldehyde (Scheme 2). The resultant propargyl alcohols (**13a-f**) were formed in fair to good yields (56-80%) except in the case of thienyl substituted **13d** (40% yield); in this case a significant amount of carbene insertion product **14** (53%) was formed competitively. Acetylation of **13a-f** under standard conditions and complexation with $\text{Co}_2(\text{CO})_8$ then afforded **8a-f** in good to excellent yields.

Two additional substrates were prepared by procedures other than the standard one. Unsubstituted **8g** was obtained by way of Sonogashira reaction between 2-iodobiphenyl and propargyl alcohol to give **13g** (87% yield) (Scheme 3), which was in turn subjected to acetylation and complexation with $\text{Co}_2(\text{CO})_8$ under conditions analogous to **13a-f**, affording **8g** in 86% yield.

Scheme 3. Formation of **8g**.

Carbomethoxy- substituted **8h**, the propargyl ether- $\text{Co}_2(\text{CO})_6$ complex envisioned as the precursor to allocolchicine itself, required a modified approach for its preparation. In this case, methyl 4-bromo-3-iodobenzoate, prepared by conventional esterification of the corresponding acid,¹⁸ was subjected to Sonogashira reaction with propargyl methyl ether to afford **15** in 92% yield (Scheme 4). The Suzuki-Miyaura reaction of this halide with 2,3,4-trimethoxyboronic acid was somewhat problematic, as convention conditions resulted in predominant boronic acid hydrolysis and recovery of substantial **15**, with only a small amount of **16** isolated (27% yield). Use of $\text{Pd}_2(\text{dba})_3$ with PCy_3 , however, gave **16** in acceptable yield (53%, 77% based on recovered starting material [brsm]), with recovery of **15** (31%). While most of the material was carried forward using this protocol, it was found

ultimately that use of the PEPPSI-*i*Pr catalyst enabled formation of **16** in 79% yield.¹⁹ Formation of **8h** was accomplished from **16** in a straightforward manner (83% yield) with Co₂(CO)₈.

Scheme 4. Preparation of **8h**.

With the Nicholas reaction precursors in hand, attention was turned to investigation of the cyclizations. Under conditions developed previously for benzocycloheptyne ring closure reactions, **8a** (0.005 M in CH₂Cl₂) underwent reaction in the presence of BF₃-OEt₂ (3 equiv), giving dibenzocycloheptyne **9a** over 2.5 h (56% yield) (Table 2, entry 1). As a small amount of decomposition was evident chromatographically during this process, and with the belief that this could be due to the acid liberated during the substitution process, the reaction was conducted with the addition of 1.5 equiv. *i*-Pr₂NEt. Although the reaction occurred somewhat more slowly (6 h) (entry 2), **9a** could be isolated in improved yield (71%). These conditions (3 equiv. BF₃-OEt₂, 1.5 equiv. *i*-Pr₂NEt, 0.005-0.01 M) were applied to **8b-8h** (Table 2), and afforded fair to excellent yields of **9b-h**. While there was some variation in required reaction time (4.5 – 16 h) and substrate, there was no particular correlation between reaction

time and substitution pattern of the arene behaving as nucleophile. In the case of trimethoxy substituted **8b**, TLC analysis suggested the onset of some decomposition without complete conversion at 16 h, so that the reaction was terminated at this point and small amount of **8b** (10%) could be recovered in addition to the isolated **9b** (59% yield) (entry 3). 3-Thienyl substituted case **8d** underwent competitive cyclization at C-2' and C-4', affording **9d** and **9d'** and a regioisomeric mixture (82%, 45:55 **9d:9d'**) (entry 5). It is also worthy of note that **8c • 9c** (entry 4) and **8g • 9g** (entry 8) proceeded uneventfully, as the less electron rich arene nucleophiles would be of borderline reactivity and insufficient reactivity, respectively, for participation in intermolecular Nicholas reactions.¹⁵ Evidence of restricted rotation about the aryl-aryl bond was present for several of the cyclization products, as all dibenzocycloheptyne- $\text{Co}_2(\text{CO})_6$ complexes bearing an additional substituent ortho to the biaryl gave diastereotopic CH_2 's for the propargylic hydrogen atoms in the ^1H NMR spectra (**9a, b, f, g**). In addition, those bearing substituents ortho to the cycloheptyne either gave a diastereotopic CH_2 (**9c**) or one right at coalescence (**9h**).

Removal of the $\text{Co}_2(\text{CO})_6$ fragment for use in synthesis require concomitant conversion of the alkyne function into one compatible with the seven-membered ring.^{20,21} The most commonly employed reagent for this purpose, Bu_3SnH , has caused some isomerization in related benzocycloheptyne cases;^{12c} consequently we chose to apply a modification of Isobe's hydrosilylation protocol²⁰ that would afford the alkene. Addition of triethylsilane to the dibenzocycloheptyne complexes **9** in the presence of bis(trimethylsilylacetylene) (BTMSE) gave a regioisomeric mixture of silylated cycloheptenes, which were not isolated, but subjected to in situ desilylation with trifluoroacetic acid (TFA) to give the dibenzocycloheptenes **17**. These dibenzocycloheptenes (**17a,e,f,h**) were isolated in good to excellent yields, and with no evidence of double bond isomerization during the reductive decomplexation process (Table 3).

^a Oxidation under Swern conditions

(oxalyl chloride-DMSO, Et₃N).

Formal synthesis of (-)-alcolchicine. Since several of the existing syntheses of allocolchicines employ the dibenzocycloheptanones (**18**) as critical intermediates, conversion of dibenzocycloheptenes **17** to **18** was considered to be the most prudent approach toward their synthesis. Hydroboration-oxidation of **17h** with BH₃-THF/H₂O₂, with further oxidation of the intermediate alcohol using PDC, afforded ketone **18h** in good yield (81%). Dibenzocycloheptanone **18h** has been converted to (-)-alcolchicine by Wulff,⁶ and as such this represents a formal synthesis of this natural product.

Similarly, treatment of **17f** by BH₃-THF/H₂O₂ followed by oxidation with PDC afforded **18f** (67% yield). Dibenzocycloheptanone **18f** is a degradation product of (-)-androbiphenylene that has been prepared previously by Seitz,²² and found to be equally potent to (-)-androbiphenylene in inhibition of tubulin assembly.

Synthesis of (-)-N-acetylcolchicine O-Methyl Ether (NSC 51046) and analog. Conversion of **17a** to ketone **18a** was accomplished by hydroboration-oxidation with further oxidation under Swern conditions (DMSO-oxalyl chloride, Et₃N), giving the ketone in 80% yield. Adopting the approach of Wulff's group towards (-)-alcolchicine, the reduction of ketone **18a** using the LiBH₄/tartrate derived boronate ester (TARB-NO₂) protocol of Singaram,²³ gave alcohol **19a** in excellent yield and enantioselectivity (96% yield, 95% ee) (Scheme 5). Substitution of azide for the alcohol function by way of zinc azide/diisopropyl azodicarboxylate (DIAD)²⁴ afforded **20a** (64%), while azide reduction (H₂, Lindlar catalyst) of **20a** and acetylation gave NSC 51046 (**2**) in 88% (93% ee), which was spectroscopically identical to literature report.¹¹ Recrystallization of **2** gave this compound in >99% ee. To our knowledge this is the first asymmetric synthesis of **2**.

Scheme 5. Completion of Enantioselective Synthesis of NSC 51046 and its 3,8,9,10-tetramethoxy isomer.

Similarly, dibenzocycloheptene **17e** was converted to an isomeric 3,8,9,10-tetramethoxyalcolchicine (**21**). Hydroboration-oxidation of **17e** and further oxidation with PDC afforded dibenzocycloheptanone **18e** in 68% yield. LiBH₄/TARB-NO₂ based reduction afforded the highly enantiomerically enriched alcohol **19e** (98% yield, 98% ee) provided an extended period substrate/TARB-NO₂ mixing and slow LiBH₄ addition protocol was followed.²⁵ Zinc azide based substitution of the alcohol afforded **20e** without incident (77% yield), while reduction and acetylation gave **21** in 79% yield (95% ee); once again, a single recrystallization enriched this compound to >99% ee. To our knowledge, this is the first example of an alcolchicine with an 8,9,10- oxygenated A ring.

In summary, intramolecular Nicholas reactions have proven to be effective in the synthesis of dibenzocycloheptyne-Co₂(CO)₆ complexes. Ready decomplexation to the dibenzocycloheptenes allows application of this methodology to the synthesis of alcolchicines or their derivatives, including tubulin-inhibiting ketone 6,7-dihydro-3,4,9,10,11-pentamethoxy-5H-Dibenzo[a,c]cyclohepten-5-one (**18f**), a formal total synthesis of (-)-alcolchicine (**1**), the enantioselective total synthesis of N-acetylalcolchicinol O-methyl ether (NSC 51046, **2**), and of the 3,8,9,10- tetramethoxy isomer of NSC 51046 (**21**).

After stirring for 4 h, petroleum ether (10 mL) and iodomethane (0.4 mL) were added, and the mixture allowed to stir for 8 h). The volatiles were removed under reduced pressure, and the residue filtered through silica gel, using 1:1 petroleum ether : Et₂O as solvent). The

filtrate was concentrated under reduced pressure to give the crude dibromide, which was used without further purification. The dibromide was dissolved in THF (20 mL), and cooled to -78 °C. Butyllithium (1.08 mL of a 2.58 M solution in hexanes, 2.79 mmol) was added, and stirring continued for 5 h. A suspension of paraformaldehyde (0.4 g, excess) in THF (5 mL) was added, and the reaction stirred for 8 h as the mixture gradually warmed to room temperature.
