Importance of the Project:
Diabetic neuropathy has major negative impacts on one’s morbidity, mortality, and quality of life (Figure 1). It is highly costly to the healthcare system.

Existing State of Knowledge:
Much work has been accomplished regarding the concurrent validity and reproducibility of this technology.11-14 Corneal nerve fibre length obtained from corneal nerve microscopy has been shown to be highly reproducible and to have a high level of diagnostic validity for the identification of neuropathy. In terms of clinical variables associated with corneal nerve morphology, previous studies have shown conflicting results. Some studies showed that there is no correlation between corneal nerve density and age, whereas others showed increasing age is associated with decreased corneal nerve density. In terms of the effect of contact lens wear on corneal nerve morphology, previous work has suggested that it has no effect. However, the parameters of corneal nerve morphology in this research did not look at nerve fibre length, but rather parameters such as hepatocyte density, nerve fibre width, and nerve fibre density. Our study is the first to examine variables specifically associated with corneal nerve fibre length.

Research Question:
Are there any variables such as age or contact lens wear that may influence corneal nerve fibre length, and thus interfere with its validity as a biomarker of diabetic neuropathy?

Methodology:
We collected clinical variables, electrophysiological exam results, as well as eye history from 64 healthy volunteers. We performed corneal confocal microscopy on these patients, manually traced the nerves on the captured images, and used an image analysis software (CCM Image Analysis tool v1.1) which was provided by Drs. R. Malik and M. Dabbagh (University of Manchester, Manchester, UK) to determine their corneal nerve fibre length. We then used univariate and multivariate linear regression analysis to determine if there are any variables associated with corneal nerve fibre length.

Findings:
We found that the corneal nerve fibre length actually is quite variable in healthy volunteers. From the univariate regression analysis, we observed that even though HbA1c (a marker of glycemic control), age and status of contact lens wear were all associated with corneal fibre length. However, HbA1c was the only variable associated with corneal fibre length in the multivariate regression analysis (Figure 6).

Figure 4. Small nerve fibers in the cornea can be visualized non-invasively with corneal confocal microscopy

Figure 6. Multivariate Regression Analysis

Conclusion:
Since HbA1c is a well-known marker of glycemic control in those living with diabetes, its strong inverse association with corneal nerve fibre length (CNFL) indicates that CNFL is a sensitive measure of nerve damage in non-diabetic individuals. Those who had shorter CNFL tend to have HbA1c in the pre-diabetic range. This helps to support the use of corneal confocal microscopy as a tool to detect early nerve injury.
