DECLARATION OF ORIGINALITY

I at this moment certify that I am the sole author of this thesis and that no part of this thesis has been published or submitted for publication.

I certify that, to the best of my knowledge, my thesis does not infringe upon anyone’s copyright nor violate any proprietary rights and that any ideas, techniques, quotations, or any other material from the work of other people included in my thesis, published or otherwise, are fully acknowledged in accordance with the standard referencing practices. Furthermore, to the extent that I have included copyrighted material that surpasses the bounds of fair dealing within the meaning of the Canada Copyright Act, I certify that I have obtained a written permission from the copyright owner(s) to include such material(s) in my thesis and have included copies of such copyright clearances to my appendix.

I declare that this is a true copy of my thesis, including any final revisions, as approved by my thesis committee and the Graduate Studies office, and that this thesis has not been submitted for a higher degree to any other University or Institution.
ABSTRACT

In this thesis, we propose two new approaches which aim at improving robustness in social fabric-based cultural algorithms. Robustness is one of the most significant issues when designing evolutionary algorithms. These algorithms should be capable of adapting themselves to various search landscapes.

In the first proposed approach, we utilize the dynamics of social interactions in solving complex and multi-modal problems. In the literature of Cultural Algorithms, Social fabric has been suggested as a new method to use social phenomena to improve the search process of CAs. In this research, we introduce the Irregular Neighborhood Restructuring as a new adaptive method to allow individuals to rearrange their neighborhoods to avoid local optima or stagnation during the search process.

In the second approach, we apply the concept of Confidence Interval from Inferential Statistics to improve the performance of knowledge sources in the Belief Space. This approach aims at improving the robustness and accuracy of the normative knowledge source. It is supposed to be more stable against sudden changes in the values of incoming solutions.

The IEEE-CEC2015 benchmark optimization functions are used to evaluate our proposed methods against standard versions of CA and Social Fabric. IEEE-CEC2015 is a set of 15 multi-modal and hybrid functions which are used as a standard benchmark to evaluate optimization algorithms. We observed that both of the proposed approaches produce promising results on the majority of benchmark functions. Finally, we state that our proposed strategies enhance the robustness of the social fabric-based CAs against challenges such as multi-modality, copious local optima, and diverse landscapes.
DEDICATION

To my loving family:

Mother: Marzieh Taghavi

Brother: Behnam Zaeri

Sister: Sheida Zaeri

Sister: Narges Zaeri
ACKNOWLEDGEMENTS

I would like to express the deepest appreciation to my supervisor Dr. Ziad Kobti, who has the attitude and the substance of a genius: he continually and convincingly conveyed a spirit of adventure regarding research and scholarship and excitement with teaching. Without his guidance and persistent help, this thesis would not have been possible.

I would like to thank my committee members, Dr. Mehdi Kargar and Dr. Kemal Tepe as the internal and external readers respectively for their support and positive attitude towards my research work.

I appreciate Mrs. Gloria Mensah, the secretary of the director and Mrs. Karen Bourdeau, the graduate secretary for their help and support whenever I needed any assistance in academic issues.

Finally, I would like to thank my family and friends for their unconditional support in every step of my life.

Introduction

Evolutionary Algorithms

Evolutionary algorithms take their roots from the evolution theory of Darwin. These algorithms try to mimic the collective behavior of natural systems. Natural processes such as natural selection, survival of the fittest, and reproduction have been subject to inspiration as the fundamental components of evolutionary problem-solving methods [Burke et al., 2005]. The basic part of all these algorithms is that they start with a randomly generated set of solutions. Then, they try to evolve the solutions through applying a set evolutionary operators such as mutation and crossover.

Evolutionary algorithms are not limited to biological processes. There is another category of evolutionary algorithms known as Swarm Intelligence (SI). These algorithms take inspiration from social behaviors of living colonies such as ants, flocks, schools, and hives [Kennedy et al., 2001]. Within these swarms, individuals have relatively simple structures, but their collective behavior usually looks very complicated. The complex behavior of a swarm emerges as a result of the interactions between the individuals over time. This complex behavior can not be easily predicted by observing the simple behaviors of the agents separately.
There are some well-known examples categorized as evolutionary algorithms:

1. Genetic Algorithms
2. Cultural Algorithms
3. Particle Swarm Optimization
4. Ant Colony Optimization
5. Honey Bee Colony

Both categories of evolutionary algorithms share the same idea of evolving some initially generated solutions. However, the difference is in the way that they manipulate and evolve individuals through applying evolutionary operators.

**Robustness in Evolutionary Algorithms**

In the evolutionary algorithms literature, robustness means that an algorithm can be used to solve many kinds of problems, with a minimum number of adjustments to address particular problems with particular qualities [Che et al., 2010]. Also, it can mean the capability of algorithms to deal acceptably with noisy or missing data [Kennedy et al., 2001]. Most of the optimization problems suffer from issues such as multi-modality and copious local optima. The most important defect that evolutionary algorithms face with is getting stuck in local optima. Evolutionary algorithms are expected to have enough flexibility (robustness) to detect the stagnation situations and deploy the strategies to get rid of them.

Swarm intelligence, as a state of the art evolutionary method, suggests the concept of self-organization improves robustness in population-based algorithms [Blum and Groß, 2015]. Self-organized algorithms are capable of coping with various search landscapes. They can learn and adapt themselves to different environments. So,
self-organized strategies allow the evolutionary algorithms to address a wide range of optimization problems in comparison with traditional methods since they need less initial parameters settings.

To evaluate how our approaches improve the robustness of evolutionary algorithms, we tested the approaches on a set of complex functions. The reported values for mean, best, and standard deviation of each function can give us a measure to see how our proposed methods improve the robustness of search algorithms against different problems.

**Research Motivation**

Our main motivation for this research work originates from scrutinizing different optimization algorithms and their capabilities of tackling various functions and search problems. As stated by No Free Lunch (NFL) theorem, there is no algorithm better than others over all cost functions [Wolpert and Macready, 1997]. It means, there is no guarantee for an algorithm to work well for all functions if it shows promising results for a particular category of them. Therefore, robustness has been one of the most desired features which motivates researchers to invent new methods which are less dependent on the kind of a problem than others. The aim of this research work is to improve robustness in evolutionary algorithms. In our thesis, we mostly emphasize on exploring different approaches to improving robustness in cultural algorithms regarding both belief and population spaces.

**Thesis Contribution**

In the thesis, we are going to improve the robustness of Cultural Algorithms in both components of population and belief spaces. In the population space, a new neigh-
The neighborhood restructuring strategy is proposed which works based on a dynamic and irregular topology. In our approach, neighborhood restructuring occurs at a microscopic level, and every individual decides to change its neighborhood size. In the belief space, a new normative knowledge source is proposed which works based on the Confidence Interval concept inspired from Inferential Statistics. Also, we recognized that both Social fabric and PSO algorithm utilize the same social structure to facilitate social interactions between the individuals. So, we decided to use PSO in the population component of our proposed approach. We hypothesize that both of our approaches help the algorithm to resist against perturbations and not get affected by the fluctuations in the search space. The first approach lets the individuals adjust their relationships autonomously (self-organization). The second method makes the normative ranges in the belief space robust against fluctuations in the input data.

Various benchmark functions have been used to evaluate the efficiency of evolutionary algorithms. As a reliable benchmark, we chose IEEE-CEC2015 function set which covers most of the desired properties for an optimization testbed such as multi-modality, copious local optima, and non-separability [Chen et al., 2014]. In our thesis, they are categorized in four categories: Unimodal, Simple multimodal, Hybrid, and Composite functions.

**Thesis Outline**

In the first chapter of this thesis, we give a general explanation of our motivation and contribution. The remaining chapters explain our research work in detail. Chapter 2 contains the related works done on the social fabric and the particle swarm optimization. This chapter is composed of 7 selected papers which 5 of them are about multi-population cultural algorithms and social fabric and how to apply them together. And, two of them are about PSO variants. In Chapter 3, we explain cultural
algorithms, social fabric, and PSO as our research background on evolutionary algorithms. Chapter 4 is composed of a detailed description of our proposed approaches to improve robustness in cultural algorithms. Chapter 5 explains IEEE-CEC2015 function set as the benchmark to evaluate the performance of our proposed methods against the standard social fabric algorithm. In Chapter 6, we present the result and comparison of the output of different methods on the benchmark functions in detail. Finally, in chapter 7, we conclude our work and suggest some new ideas for future works.
Chapter 2

Related Works

Many variants of CAs have been proposed in a vast range of different applications such as single and multi-objective optimization, dynamic problems, social interactions simulation. Here, we are interested in studying socially motivated and multi-population variants as some modern approaches in solving optimization problems.

Cultural Algorithms

Heterogeneous Multi-Population Cultural Algorithm

[Raeesi and Kobti, 2013] proposed a new architecture for cultural algorithms. In this approach, the whole population is divided into a set of independent sub-populations which work in parallel without direct communication. They referred to the works of [Xu et al., 2010], [Guo et al., 2011], [Vasile et al., 2011], and [Sharma et al., 2011]. As their motivation they stated that most of proposed variants of evolutionary algorithms suffers from immature convergence. This occurs because these algorithms can not hold the diversity at a reasonable level. Based on existing research works, they hypothesized that multi-population strategies would be a better choice as they have the potential to perform an efficient search on complex landscapes. In their approach,
the optimization parameters are divided among some heterogenous sub-populations. The sub-populations are called heterogenous because each sub-population is responsible for optimizing a different subset of parameters. Each sub-population represents a partial solution instead of a complete solution. To evaluate a partial solution, it gets completed by its complement parameter values from the belief space. The complete solution is evaluated based on a numerical optimization function. Also, to make the convergence process faster a simple local search strategy is incorporated into the proposed algorithm. The general architecture of their algorithm is presented in Figure 2.1

In the experiments, they considered the whole population size to be 1000 individuals. It is divided into 30 sub-populations. So, the size of each sub-population is 33. The algorithm runs for the maximum of 10000 generations and the local search strategy runs only for 10 iterations. They evaluated HMP-CA on a set of 8 complex optimization functions. It is able to find the minimum value for 7 functions out of 8. However, when the local search strategy is applied to the experiments, the proposed method outperforms all of the functions and it finds the optimum value very quickly. Ultimately, they claimed that their proposed approach is efficient in both time and space complexity.

Figure 2.1: H-MPCA Architecture [Raeesi and Kobti, 2013]
The Social Fabric Approach as an Approach to Knowledge Integration in Cultural Algorithms

[Reynolds and Ali, 2008] begins with a brief introduction to socially motivated methods to problem solving. They referred to the works of [Hu et al., 2003], [Reynolds and Ali, 2007], and [Cheng et al., 2005]. It compares qualities of Ant Colony Optimization (ACO), Particle Swarm Optimization (PSO), and Cultural Algorithms (CA) regarding the scale in which the interactions between agents occur. Figure 2.2 compares PSO, ACO, and CA in terms of the time and space continuum over which the social interactions occur. Individuals in ACO and PSO tend to interact in a relatively limited temporal and spatial scales. It is obvious because the agents in both ant and particle swarm algorithms exchange information with only other agents in their local neighborhood. On the other hand, cultural algorithms let the individuals interact together using various types of symbolic information emerged from complex cultural systems. In cultural algorithms the interactions among individuals occur indirectly through a shared belief space. So, cultural algorithms allow individuals interact in a global scale. Then, they asked the essential question of what social structures might emerge alongside the search process?. To answer such questions, they introduced

Figure 2.2: Scale of social interactions [Reynolds and Ali, 2008]
a new influence function which utilizes the social fabric phenomena. The old influence function assumes no interactions between agents and works based on the simple roulette wheel method. On the other hand, in the new influence function, the individuals are connected through a social network (fabric). Multiple layers of such networks could be employed in a population. The interplay of these network connection forms a social fabric. At each iteration, an individual could specify its controller knowledge source. In this approach, the controller knowledge source is chosen based on the majority of knowledge sources in the neighborhood of an individual. The neighborhood size of an individual is specified by the topology of the fabric. Inspired by Particle Swarm Optimization literature, different topologies could be taken into consideration to model the relationships among individuals. In their work, they only considered Ring and Square topologies. They stated that, the topology of the social fabric determines the extent to which the influence of knowledge sources could be spread through the network.

To evaluate the social fabric approach, they implemented it in Repast framework. Repast is a simulation tool for multi-agent systems. They created a cultural algorithms toolkit (CAT) to view the capabilities of cultural algorithms in solving various problems. They chose Cone World problem to evaluate and compare their approach with the standard cultural algorithm. The reason that they chose this problem is that by changing its parameters during the evolution process, it can show a dynamic behavior. So, Cone World problem provides an efficient way to test flexibility of search algorithms. They set the parameters of CAT as: 100 individuals, 100 cones and 1000 generations. They used ring and square topologies to form the social fabric. They stated that square topology works better than ring as it finds the solution after 250 iterations. While, the ring topology finds the best solution 450 iterations.
Robust Evolution Optimization at the Edge of Chaos: Commercialization of Culture Algorithms

[Che et al., 2010] aimed at commercializing Cultural Algorithm Toolkit (CAT) through developing a robust variant of it. By robustness, they mean to develop a cultural algorithm which is capable of being applied across a vast range of complex problems. At first, they referred to [Peng, 2005] as an standard model cultural algorithms which assumes no connection between individuals. Then, they referred to [Ali, 2008], which introduced the concept of social fabric to allow individuals interact together. The authors extended the work of Ali by allowing the social networks having a memory. In addition, they utilized a variety of different networks in order to determine the relationship between network and problem complexity.

They brought up the hypothesis that there might be multiple independent networks for different purposes such as kinship and economics. In such networks, there are always some individuals which are member of multiple networks and so, they can play the role of mediator between different networks. To preserve the diversity, the authors utilized a variety of different topologies such as Lbest, Square, Hexagon, Octagon, Hexadecagon, and Gbest.

They stated that in the previous work of [Ali, 2008], he employed an un-weighted majority win strategy to determine the controller knowledge source of an individual. It just relied on the count of each knowledge source in the neighborhood of each individual. The authors replaced it with a new strategy which use the average fitness of each KSs instead of each KSs count. So, the performance of individuals in a neighborhood influences which knowledge source to be chosen for the next iteration.

To evaluate the robustness of the algorithm, the authors used Cone World Generator [Morrison and De Jong, 1999] as a dynamic problem. Refered to the work by [Lewin, 1999], they defined three classes of entropy in the cones world problem:
1. Fixed: There is a low entropy and the parameters of the environment do not tend to change at all.

2. Periodic: The environment parameters change in a regular period of time. So, the algorithm should be capable adapting itself regularly.

3. Chaotic: In this case, the parameters change without any order and no prediction could be made about them. In fact, it is more similar to real-world cases.

For the fixed category, the square topology successfully solved 84% of the problems and as the best topology. For the periodic case, the octagon topology showed a better performance than other toplogies. And, for the chaotic category, Gbest showed a better result mostly in terms of average time to find a solution and the standard deviation. In summary, as the complexity of problems grows, there is the need for more connections between individuals in a social fabric to keep the robustness of the algorithm.

Socio-Cultural Evolution via Neighborhood-Restructuring in Intricate Multi-Layered Networks

[Ali et al., 2012] aimed at exploring the utilization of neighborhoods in the population level of cultural algorithms and see how it influences the knowledge swarming in the belief space. Their approach uses a dynamic neighborhood restructuring to preserve diversity efficiently. They referred to the research works of [Elsayed et al., 2011], [Asafuddoula et al., 2011], and [Asafuddoula et al., 2011]. Those papers proposed some adaptive methods which tried to make a trade-off between exploration and exploitation properties of evolutionary algorithms. Among the referred papers, the work by [Ali et al., 2010] used the social fabric phenomena to from multi-layered hierarchical network structures in both homogenous and heterogeneous networks.
Figure 2.3 describes the multi-layered structure.

The authors defined the social fabric phenomena as follows:

'The Social Fabric is a living informational skin created out of the engineered emergence of agents illustrating the tension between the individual and the community in a context of interaction between them.'

The informational skin is created by the connectivity of individuals together. The social fabric is used to combine the behaviors at both individuals and society levels. Then, they proposed a strategy to determine the controller knowledge source of each individual in each generation. In the strategy, the agents send the name of their controller knowledge source to their neighbor through the social fabric. Each individual picks the mostly used knowledge source in its neighborhood as its controller for the next iteration. In case of a tie between two or more knowledge sources, three tie-breaking strategies are introduced:

1. Most Frequently Used (MFU)
2. Random
3. Least Frequently Used (LFU)
They stated that their proposed approach is inspired from a previous work of [Reynolds et al., 2008]. The new idea was called Cultual Algorithm with Restructuring Layered Social Fabric (CARLSOF). In this approach, the whole population is divided into two layers of rudimentary and advanced members. There are some independent tribes in the population space which their best performing individuals form the advanced layer and the others form the rudimentary level. In the previous works, the topology of social fabrics were supposed to be fixed and homogenous. They utilized a variety of regular topologies to form the social fabric. The authors proposed a new strategy to enable the fabric to be restructured in the case of stagnation. Each tribe may decide to change its topology to a denser (with more connections) or sparser (with less connections). They referred to two different restructuring strategies as similar approaches. The first one was Layered Delaunay Triangulation which is based on voronoi diagram. The second approach was Random Rewiring Procedure which starts with a regular topology and then rewire each edge randomly with the probability $p$.

To evaluate the performance of CARLSOF, they used function set of IEEE-CEC2011 evolutionary competition. The algorithm was implemented in JAVA. The authors reported that CARLSOF was successful to enhance all of the functions in the testbed in terms of average, best, and worst obtained values. Also, they claimed that CARLSOF outperforms the best previously obtained results for European Space Agency (P12) and Casini (P13) problems results. They reported 2.983 km/sec compared to previous best 7.095. For p13, they reported 8.383091 km/sec compared to previous best 8.3832.

[Ali et al., 2016] made an overall review of related works on Cultural Algorithms and Social Fabric [Peng, 2005], [Reynolds and Ali, 2008], [Chen et al., 2006], and [Kennedy, 1999]. They introduced the concept of social fabric as an infrastructure which facilitates the propagation of the influence of the knowledge sources through the population space. The whole population is divided into multiple small sized tribes. Unlike other PSO-based multi-swarm variants, the tribal sub-swarms change their topology during the evolution process to keep diversity against stagnations. The tribes are organized in a two-layer structure of advanced and rudimentary classes. The advanced class is composed of best performing individuals of each tribe. From each tribe, two examplars are chosen. The first one is the best of explorer knowledge sources (Normative and Topographic) and the second one is the best of exploiter knowledge sources (Situational). Figure 2.4 describes the two-layer structure. The authors utilized only three kinds of knowledge sources: Normative, Topographic, and Situational. They claimed that, other types of knowledge sources are suitable for dynamic problems. However, they used a set of static problems to evaluate their approach. The authors divided the evolution process of CAs into three stages: the seclusion stage, the rapport stage, and the cohesive stage. In the seclusion stage, the tribes evolve independently and without any exchange of information. Then, in the rapport stage, the tribes start to exchange knowledge via the advanced class. Also, the neighborhood restructuring strategy is launched in each tribe. So, the tribes have the capability to restructure their topology to keep diversity and avoid local optima. The first two stages ensure that diversity has been kept in the initial iterations of the search process. Finally, in the third stage, all the tribes are merged together.
and continue the search process as a single CA model. Based on the categorization proposed in [De Oca et al., 2009], the authors claimed that their approach is heterogeneous regarding update-rule heterogeneity and neighborhood heterogeneity. Since the topology of each tribe is changing during the evolution process, the tribes might use different topologies at the same time. So, it could be considered as heterogeneous neighborhood restructuring. Also, their approach utilizes update-rule heterogeneity because, there are individuals with different roles (explorer and exploiter).

In the experimental results section, the authors used IEEE-CEC2011 competition on testing evolutionary algorithms on real-world numerical optimization problems. They presented an extended comparison of their approach with other proposed methods. At first, the authors tested the approach (T-SCANeR) with different values for these parameters: tie-breaking rule, $M_{\text{thresh}}$, and number of elites. There is no best value for tie-breaking rule as it is problem-dependent. For the $M_{\text{thresh}}$ parameter, the results show that the best value is 50. The best value for $n_{\text{elite}}$ is 2. The second experiment was on varying the window size within which the social fabric is applied and aggregated ($W_{\text{size}}$). The best reported value for $W_{\text{size}}$ is 20.

In the two first experiments the best values for the parameters were determined. Based on the obtained values, the authors compared T-SCANeR with five other evolution-
ary algorithms on the IEEE-CEC2011 which is a set of 18 functions. T-SCANeR managed to outperform for most of the functions except for $T_3$, $T_4$, $T_6$, and $T_{11.5}$. Problems $T_{12}$ (full messenger problem) and $T_{13}$ (cassini problem) are associated with the European Space Agency (ESA). The authors claimed that T-SCANeR outperformed other methods by 2.193724 km/s for the messenger problem and 8.383090 for the cassini problem.

**Particle Swar Optimization**

**Tribe-PSO: A novel global optimization algorithm and its application in molecular docking**

[Chen et al., 2006] proposed a new variant of Particle Swarm Optimization (PSO) called Tribe-PSO for the primary purpose of molecular docking in chemometrics. As some previous research work, they referred to [Jones et al., 1997] and [Clerc and Kennedy, 2002]. Their approach is inspired from Hierarchical Fair Competition concept [Jianjun et al., 2002]. They divided the whole population into some tribes and the evolution process into three phases. The tribes are organized into two layers of basic and upper individuals.

The individuals in each tribe are completely isolated from other tribes. So, they form the basic layer. On the other hand, the best members of each tribe can see the other tribes and exchange information with their best members as well. The problem-solving process is divided into three phases: isolated, communing, and united. In the first phase, the tribes are completely isolated and there is no exchange of information. In the second phase, the two-layered model is formed and the tribes begin to exchange information through their best performing individuals. In the third phase, all the tribes are merged into a single popualtion. Then, it operates as basic PSO model
until meeting some stopping criteria. The authors claimed that their approach helps the individuals preserving diversity and avoiding local optima against multi-modal solution spaces.

The authors used two testbeds to evaluate and compare the performance of Tribe-PSO with standard PSO. The first was De Jong’s function set and the second was a test set of 100 receptor-ligand X-ray structures selected for docking benchmark. In the De Jong’s testbed, the basic PSO showed a better performance in the isolated phase. However, in the communing phase Tribe-PSO converged to a better value than basic PSO. In the unity phase, the basic PSO seemed to get stuck in a local optimum. However, Tribe-PSO continued to accelerate convergence and got better results than basic PSO. In the docking benchmark, Tribe-PSO was compared to the AutoDock library. Four parameters are calculated after 10 independent runs: Best, Run1, Average, and Standard Deviation of the results. The relative difference of the four benchmark factors between Tribe-PSO and AutoDock were calculated. The results for the four factors showed that Tribe-PSO leads to a better performance than AutoDock.

**Heterogeneous Particle Swarm Optimizers**

[De Oca et al., 2009] presented a survey on heterogeneous variants of Particle Swarm Optimization (PSO). They claim that the homogenous models have been attractive because of their simplicity in conceptual and application levels. However, heterogeneous models are ubiquitous in nature. Here, heterogeneity means the individuals may differ from each other regarding their parameters and search behavior.

At first, the authors presented a brief description of three well-known variants of PSO: Accelerated PSO [Zhang et al., 2003], Fully-informed PSO [Mendes et al., 2004], and Bare Bones PSO [Kennedy, 2003]. Then, they authors categorized the heterogeneous variants of PSO into four categories:
1. Neighborhood

2. Model of Influence

3. Update Rule

4. Parameters

Neighborhood heterogeneity refers to the cases that the topology of the swarm is not regular. This type of heterogeneity occurs when the neighborhood size of each individual is different. They claimed that the neighborhood heterogeneity allows some population to be more influential than others. Individuals with higher number of connections have the potential to attract more individuals through the search process [Kennedy et al., 2001].

Model of Influence heterogeneity refers to the situations that the individuals employ different strategies to specify their informers. The word Informer refers to an individual which is going to influence another individual.

Update-rule heterogeneity means the individuals utilize different strategies to update their position in the search space. This kind of heterogeneity makes it possible for the individuals to explore the search space in several ways. Also, the particles can play different but complementary roles. For example, some of them may tend to explore unseen parts of the solution space and some others only follow those scout individuals. The second type are the exploiters.

Parameter heterogeneity occurs when some individuals in a group which follow the same update rule use different update rule’s parameter settings. Having different search parameters, even in a group of similar particles, leads to various search behaviors which improves the level of diversity. The authors referred to [Mendes, 2004] and [Montes de Oca and Stützle, 2008] which utilize different initial values for the parameters such as acceleration coefficient, maximum velocities and inertia weight.

To compare the mentioned categories, the authors careded two test cases. The first
one compared two PSO variants with different update rules: Velocity-based and Bare bones swarm. The evaluation results confirmed that velocity-based outperformed the other one. The second test case compared two PSO variants with different models of influence: best-of-neighborhood and fully-informed swarm. The evaluation results showed that the fully-informed algorithm outperformed the best-of-neighborhood.

Chapter Conclusion

From the chosen research works, we will be utilizing the concept of heterogeneous neighborhood structures by [De Oca et al., 2009] to improve the robustness of social fabric-based cultural algorithm [Ali et al., 2016]. We replace the population component of [Ali et al., 2016] with PSO algorithm.
Chapter 3

Evolutionary Algorithms

This chapter presents a detailed description of related evolutionary algorithms such as cultural algorithms, particle swarm optimization, and their social variations. In this section, we try to give a brief description of those evolutionary algorithms as a background to our proposed approaches.

Evolutionary Algorithms

Evolutionary computing is a research area within computer science. As the name suggests, it is a particular flavor of computing, which draws inspiration from the process of natural evolution. In fact, they are computer programs which try to solve and optimize complex problems by simulating the behavior of natural systems. They utilize evolutionary operators such as crossover and mutation to improve the quality of a population of solutions [Burke et al., 2005].

Evolutionary algorithms start with a population of randomly generated solutions for a particular problem. Then, the algorithm modifies the solutions in an iteration-based process of some finite number of generations. The modification occurs through applying the so-called evolutionary operators such as crossover and mutation. The evolutionary operators might be binary or unary. For example, the crossover is a bi-
nary operator because it combines two solutions (individuals) to generate a new one. On the other hand, mutation is a unary operator because it makes random modifications on a single solution to improving its performance [Eiben and Smith, 2003]. The performance of each is evaluated using a fitness function. The fitness function represents the problem that needs to be solved or optimized. Usually, the fitness function is chosen from NP problems which are hard to solve by traditional problem-solving methods. In each iteration of an evolutionary algorithm, the evolutionary operators are applied to the individuals and the best performing offsprings will be transferred to the next generation. This process continues until meeting some stopping criteria which are already defined by a human user. Some examples of evolutionary algorithms are:

1. Genetic Algorithms

2. Evolutionary Programming

3. Differential Evolution

However, the evolutionary algorithms are not restricted to biological processes. Some researchers have drawn inspiration from social systems to find solutions to complex problems. The complex and coordinated behavior of swarms not only fascinates biologists but also is an inspiration to computer scientists [Bonabeau et al., 1999]. Ant colonies and birds flocking are remarkable examples of coordinated collective behavior that emerges without centralized control. Swarm intelligence is a field of computer science that invents computational methods for solving problems in a way that is inspired by the behavior of real swarms and colonies. Principles of self-organization and communication (local and indirect) are essential to understanding the complex collective behavior [Stützle, 2009]. There are different types of swarm-based algorithms such as:

1. Particle Swarm Optimization (PSO)
2. Ant Colony Optimization (ACO)

3. Cultural Algorithms (CA)

Cultural Algorithms

Cultural Algorithms (CA) were introduced by Reynolds as a type of population-based problem-solving approaches. CA combines biological evolution with socio-cognitive concepts to yield an optimization approach based on a dual inheritance theory [Reynolds, 1994]. As defined by [Durham, 1991], culture is a “system of symbolically encoded conceptual phenomena that are socially and historically transmitted within and between populations”. From the definition, it can be stated that in cultural systems, evolution occurs at two levels: Macro-evolutionary level and micro-evolutionary level. Cultural algorithms define the evolution process through the cooperation of three distinct components:

1. Belief Space (Macro-evolutionary Level)
2. Population Space (Micro-evolutionary Level)
3. Communication Protocol

Belief Space

Belief space keeps different kinds of knowledge obtained from the individuals’ experience during the evolution process. It extracts the knowledge from the population and stores the knowledge in various formats called knowledge sources (KS). Each knowledge source extracts and keeps knowledge about a particular aspect of the search space.

After each iteration, the best performing individuals are chosen and sent to the belief space to be utilized by the knowledge sources. The stored knowledge is used to bias...
the search process in the population space. Five types of knowledge sources have been identified in the belief space:

1. Situational Knowledge: Successful exemplars of individuals
2. Normative Knowledge: The best range of value for each parameter
3. Topographic Knowledge: The best areas of the search space
4. Domain knowledge: The domain ranges for all the parameters and the best exemplars
5. Temporal Knowledge: Knowledge about the past changes in a dynamic environment

Population Space

In the population space, any population-based algorithm could be used. In the earlier variants of cultural algorithms, only GA was used. However, researchers utilized other population-based algorithms such as PSO and EP in the population component. In each generation, the best individuals are sent to the belief space to update the knowledge sources. Then, the belief space influences the population through the search process. Figure 3.1 describes the components of cultural algorithms.

Communication Protocol

In cultural algorithms, the belief space and the population communicate together through a two-way protocol. The population space sends the best individuals to the belief space using the acceptance function to update the knowledge sources. Then, the belief space bias the search direction of the population space through the influence function.
Social Fabric-based Cultural Algorithms

Social Fabric is a dynamic grid of information flow in which the individuals’ interactions happen. The fabrics (networks) are created by the connectivity of each agent with other agents in a dynamic structure. The topology of the network controls the rate and type of interactions [Reynolds and Ali, 2008]. Like a multi-population model, there are multiple independent subpopulations (tribes) which are networked together [Ali et al., 2012].

In the Social Fabric idea, the influence of the belief space is propagated through the population using a multi-layered network of connections. There are $Z$ tribes comprised of $H$ individuals which form two layers: rudimentary and advanced [Ali et al., 2012] [Ali et al., 2016]. The members of each tribe are connected in a regular topology independent from other tribes. At this level, they form the rudimentary layer. From each tribe, the best performing individuals (elites) are connected. These connections create the advanced layer which is responsible for mediating the flow of information between different tribes.
Evolution Phases

The whole evolution process is split into three phases: seclusion, rapport, and cohesive. In the first stage, each tribe evolves as an independent basic CA model with no communication between tribes. In the second step, the advanced layer is formed by connecting elites of each tribe. Then, tribes start to exchange information during their evolution process. Ultimately, in the third step, all the tribes are merged into one CA model. Then the search process continues until meeting some stopping criteria.

Strategic Neighborhood Restructuring

In Social Fabric literature, Strategic Restructuring is a technique to help individuals to get rid of stagnation where there are copious local optima in the search landscape. Each tribe maintains a particular topology until it gets stagnated in a local optimum for a certain number of iterations. Then, the topology is reinitialized to motivate the individuals for a new search. Here, four types of topologies are utilized: Ring, Mesh, Hybrid-Tree, and Global [Ali et al., 2016]. Figure 3.2 describes how the process of neighborhood restructuring occurs.

Figure 3.2: Standard Neighborhood Restructuring Process
Social fabric based influence function

In this model, the individuals might decide to change their controller KS using the majority of KSs which they receive from their neighborhood. Here, Majority Voting is used to find the controller KS of an individual [Che et al., 2010]. Figures 3.3 describes the social fabric influence function. In the case of a tie, some tie-breaking rules are deployed such as MFU (most frequently used), LFU (least frequently used), Direct (the direct influencing KS), Random (a random choice), Last-used (the KS which controlled the KS in the last iteration) [Ali et al., 2012]. In the equation 3.1 the sum denotes the counts of KSs in \( i \)th node neighborhood and \( \psi_i \) is its controller KS. \( \tau_i \) is the net affecting KS for the next iteration [Ali et al., 2016] [Sterling, 2004].

\[
\tau_i = \sum_{j \in \text{Nbr}(i)} m_{ij} + \psi_i \quad (3.1)
\]

The Social Fabric approach can be generalized on different topologies as follows:

\[
KS(t+1) = \begin{cases} 
KS_i, & \forall KS_j \in \{KS - KS_i\} \Rightarrow weight(KS_i) > weight(KS_j) \\
KS_{cr}, & \text{otherwise}
\end{cases} \quad (3.2)
\]

Where \( KS \) is the set of all knowledge sources, \( KS_i, KS_j \in KS \). \( weight(\bar{U}_i KS_i) \) is the number of neighbors that belong to the knowledge source \( KS_i \). \( KS_{cr} \) denotes the knowledge source chosen by a tie-breaking rule.

Particle Swarm Optimization

The initial idea for particle swarm optimization of Kennedy and Eberhart were essentially aimed at producing computational intelligence by utilizing simple models of social interaction, rather than purely single-agent cognitive capabilities.
In PSO, some simple-structured individuals (the particles) moving around in the search space of a function, and each particle evaluates the objective function based on its current location. Then, each particle determines its movement direction and velocity through the search space by combining its historical best experience and the best (best-fitness) particle in its visible neighborhood in the swarm, with some random fluctuations for keeping diversity. This process repeats at each iteration. Eventually, the swarm as a whole, like a flock of birds collectively searching for food sources, is similar to move around for finding an extremum of the fitness function.

Each particle is comprised of a position vector and velocity vector [Bratton and Kennedy, 2007]. Particles adjust their velocities and positions as follows:

\[
\begin{align*}
v_{id}^{(t+1)} &= w \cdot v_{id}^{(t)} + c_1 r_1 (p_{id} - x_{id}^{(t)}) + c_2 r_2 (p_{gd} - x_{id}^{(t)}) \quad (3.3) \\
x_{id}^{(t+1)} &= x_{id}^{(t)} + v_{id}^{(t+1)} \quad (3.4)
\end{align*}
\]
Where $v_{id}$ and $x_{id}$ are the velocity and position of $i$th particle. $c_1$ and $c_2$ are two positive constants. $r_1$ and $r_2$ are randomly generated numbers in $[0,1]$ range. $w$ is the inertia weight of which restricts the velocity of a particle. $p_{id}$ is the best experience of the particle and $p_{gd}$ is the best solution in its neighborhood. Figure 3.4 describes how the particle interact together in PSO.

![Figure 3.4: Social interaction model of PSO](image)

**Tribe-PSO**

Similar to Social Fabric model, the whole population is divided into some tribes. The tribes form a two-layer structure of networks, and the whole process consists of three phases [Chen et al., 2006]. The individuals in each tribe are completely isolated from other tribes. So, they form the basic layer. On the other hand, the best members of each tribe can see the other tribes and exchange information with their best members as well. The problem-solving process is divided into three phases: isolated, communing, and united. In the first phase, the tribes are completely isolated and there is no exchange of information. In the second phase, the two-layered model is formed and the tribes begin to exchange information through their best performing individuals. In the third phase, all the tribes are merged into a single population. Then, it operates as basic PSO model until meeting some stopping criteria. In fact, the idea of Social Fabric originates from Tribe-PSO. But the network structure is utilized to propagate the influence of knowledge sources in the belief space [Ali et al.,
In the thesis, we use the social fabric for both PSO interactions and knowledge propagation of the belief space. Figure 3.5 describes the architecture of Tribe-PSO.

Figure 3.5: Tribal-PSO

Chapter Conclusion

This chapter presents a detailed description of evolutionary and social methods such as cultural algorithms, social fabrics, and PSO. The chapter was focused on Tribal variants of before mentioned approaches and how to deploy social relationships among the tribes’ members.
Chapter 4

Proposed Approaches: Improving Robustness in Social Fabric

Inspired by natural systems, many evolutionary algorithms have been proposed to solve various optimization problems. These algorithms are expected to exhibit a consistent problem-solving behavior against different optimization landscapes. Unfortunately, as stated by No Free Lunch (NFL) theorem by [Wolpert and Macready, 1997], there is no algorithm better than others over all cost functions. It means, there is no guarantee for an algorithm to work well for all functions if it shows promising results for a particular category of them. Therefore, robustness has been one of the most desired features which motivates researchers to invent new methods which are less dependent on the kind of a problem than others. Here, robustness means we need to develop search strategies which are capable of adapting themselves across different landscapes which might vary regarding aspects such as multimodality and the number of local optima.

In this section, we are going to improve the robustness of CAs in both population space and belief space components. In the population space, a new neighborhood restructuring strategy will be proposed which aims at microscopic inspections for
stagnation regarding individuals’ local experience. Then, in the belief space, a new model of Normative KS will be proposed, which defines the normative ranges based on Confidence Interval inspired from Inferential Statistics. It stops the normative KS to be affected by sudden fluctuations in the input data.

Self-organization

A self-organized system is a group of agents with specific behavioral patterns which could not be predicted from the simple behaviors of the individuals who make up the system. [Kennedy et al., 2001] described self-organization as follows:

'Self-organization The ability of some systems to generate their form without external pressures, either wholly or in part. It can be viewed as a system’s constant attempts to organize itself into ever more complex structures, even in the face of the constant forces of dissolution described by the second law of thermodynamics.'

Some of the primary attributes of self-organizing systems are listed below:

1. Self-organizing systems usually exhibit the behaviors that appear to be spontaneous order.

2. Self-organization can be considered as a system’s constant attempts to organize itself into a variety of complex structures, even in the face of the forces of deviation (Robustness).

3. The overall status of a self-organizing system is an emergent property of all the ingredients of the system.

4. Interconnected components of the system become organized in a meaningful way based on local interactions of the components.
5. Complex systems have the potential to self-organize themselves.

6. The self-organization process works close to the 'edge of chaos'.

In the section, we will propose a new approach to improve the robustness of cultural algorithms regarding self-organization.

**Irregular Neighborhood Restructuring**

As proposed by [Ali et al., 2016], when the agents of a tribe get stuck in a local optimum, then they choose a topology with fewer connections such as ring topology to motivate exploration. When the agents lack information, the topology is changed to a denser topology like Mesh, and ultimately Global. Whenever a tribe does not make progress for $M_{thresh}$ iterations, then the algorithm decides on upgrad- ing/downgrading the current topology to other topologies. Downgrading happens by moving in the direction of $\text{gbest} \rightarrow \text{tree} \rightarrow \text{mesh} \rightarrow \text{lbest}$ and Upgrading occurs in the direction of $\text{lbest} \rightarrow \text{mesh} \rightarrow \text{tree} \rightarrow \text{gbest}$. In our proposed approach, the restructuring process occurs at a microscopic level. There is no daemon process for inspecting stagnation. Every agent checks its performance for stagnation. If it gets stuck in a local optimum, it decides to upgrade/downgrade its neighborhood. The proposed strategy is described in the algorithm 1. If the particle is the best in its neighborhood, it starts to decrease the number of connections to motivate exploration. However, if it is not the best, it needs to increase the neighborhood size to facilitate exploitation. Here, the topology is dynamic and irregular and the neighborhood size is different for each agent. So, it could be considered as a heterogeneous variant of CAs [De Oca et al., 2009]. The ultimate topology of the fabric is formed through local interactions of the agents. In this way, it improves the robustness of CAs regarding self-organization concept [Kennedy et al., 2001]. Psudo-code 1 describes the irregular neighborhood restructuring algorithm in detail.
if $\text{fitness}(x_i) > \text{bestSoFar}_i$ then
    if $\text{stagnationCounter} \geq \text{TiggerThreshold}$ then
        if $x_i = x_{\text{best}}$ then
            index = selected randomly from $x_i$'s neighborhood
            remove $x_{\text{index}}$ from $x_i$'s neighborhood
        else
            index = selected from \{ $S - x_i$'s neighborhood \}
            add $x_{\text{index}}$ to $x_i$'s neighborhood
        end
        $\text{stagnationCounter} = 0$
    else
        $\text{stagnationCounter} = \text{stagnationCounter} + 1$
    end
else
    $\text{stagnationCounter} = 0$
end

Algorithm 1: Irregular Neighborhood Restructuring
Confidence based Normative Knowledge Source

The current version of Normative KS is quite vulnerable to temporary fluctuations in the pattern of input data. The size of Normative ranges is subject to change dramatically with any temporal fluctuations. In this section, we are going to replace the ranges in the standard Normative KS with Confidence Interval from Inferential Statistics. Confidence-based changes are more robust against instantaneous changes in the input pattern. The update process of standard normative ranges is as follows:

\[
lb_j(t + 1) = \begin{cases} 
   x_{i,j}(t), & x_{i,j}(t) \leq lb_j(t) \text{ or } f(X_i) < PL_j(t) \\
   lb_j, & \text{otherwise}
\end{cases}
\]  

(4.1)

\[
ub_j(t + 1) = \begin{cases} 
   x_{i,j}(t), & x_{i,j}(t) \geq ub_j(t) \text{ or } f(X_i) < PU_j(t) \\
   ub_j, & \text{otherwise}
\end{cases}
\]  

(4.2)

The following is the definition of normative ranges based on Confidence Interval concept [Proakis, 1985].

\[
lb_j = \bar{x}_j - q \cdot \frac{\sigma_j}{\sqrt{n}}
\]  

(4.3)

\[
ub_j = \bar{x}_j + q \cdot \frac{\sigma_j}{\sqrt{n}}
\]  

(4.4)

where \( \bar{x}_j \) is the mean of \( j \)th dimension, \( \sigma_j \) is the standard deviation of \( j \)th dimension and \( q \) is the confidence coefficient.
Chapter 5

Experimental Setup

In this chapter, we explain the experimental setup, how to set the parameters and the optimization functions as the benchmark to evaluate the efficiency of our proposed approaches.

Description

In this section, we describe IEEE-CEC2015 as the function set which we have chosen for our benchmark optimization purpose [Chen et al., 2014]. IEEE-CEC2015 is a set of 15 functions with different properties such as multi-modality, copious local optima, and non-separability. All test functions are minimization problems defined as follows:

\[ Y = f(x_1, x_2, x_3, \cdots, x_D) \]  

(5.1)

where \( D \) is the number of dimensions.

Before evaluation, all the vectors are shifted and rotated as described in [Chen et al., 2014]. \( \mathbf{o}_i = [o_{i1}, o_{i2}, \cdots, o_{iD}] \) is the shifted global optimum, which is randomly distributed in \([-80, 80] \) \( D \). For convenience, the same search ranges are defined for all test functions as \([-100, 100]^D\).
Benchmark Functions

In this section, we describe the IEEE-CEC2015 functions and their properties as a well-known benchmark adopted by many researchers to evaluate innovative ideas in solving complex optimization problems.

Unimodal Functions

Rotated Bent Cigar Function

\[ f_1(x) = x_1^2 + 10^6 \sum_{i=2}^{D} x_i^2 \]  
\[ F_1(x) = f_1(M(x - o_1)) + F_1^a \]  

Properties:
1. Unimodal
2. Non-separable
3. Smooth but narrow ridge

Rotated Discus Function

\[ f_2(x) = 10^6 x_1^2 + \sum_{i=2}^{D} x_i^2 \]  
\[ F_2(x) = f_2(M(x - o_2)) + F_2^a \]  

Properties:
1. Unimodal
2. Non-separable
3. With one sensitive direction
Simple Multimodal Functions

Shifted and Rotated Weierstrass Function

\[ f_3(x) = \sum_{i=1}^{D} \left( \sum_{k=0}^{k_{\text{max}}} a^k \cos(2\pi b^k (x_i + 0.5)) \right) - D \sum_{k=0}^{k_{\text{max}}} \left[ a^k \cos(2\pi b^k \cdot 0.5) \right] \]  
where \( a=0.5, \ b=3, \) and \( k_{\text{max}}=20. \)

\[ F_3(x) = f_3\left( M\left( \frac{0.5(x - a_3)}{100} \right) \right) + F_3^* \]  

Properties:

1. Multi-modal
2. Non-separable
3. Continuous but differentiable only on a set of points

Shifted and Rotated Schwefel’s Function

\[ f_4(x) = 418.9829 \times D - \sum_{i=1}^{D} g(z_i), \quad z_i = x_i + 4.209687462275036e + 002 \]  
\[ F_4(x) = f_4\left( M\left( \frac{1000(x - a_4)}{100} \right) \right) + F_4^* \]  

Properties:

1. Multi-modal
2. Non-separable
3. Local optima’s number is huge and second better local optimum is far from the global optimum.
Shifted and Rotated Katsuura Function

\[ f_5(x) = \frac{10}{D^2} \prod_{i=1}^{D} \left( 1 + i \sum_{j=1}^{32} \frac{|2^j x_i - \text{rand}(2^j x_i)|}{2^j} \right)^{\frac{10}{D^2}} - \frac{10}{D^2} \]  
(5.10)

\[ F_5(x) = f_5(M\left(\frac{5(x-o_5)}{100}\right)) + F^*_5 \]  
(5.11)

Properties:

1. Multi-modal
2. Non-separable
3. Continuous everywhere yet differentiable nowhere

Shifted and Rotated HappyCat Function

\[ f_6 = \left| \sum_{i=1}^{D} x_i^2 - D \right|^{0.25} + \frac{0.5 \sum_{i=1}^{D} x_i^2 + \sum_{i=1}^{D} x_i}{D + 0.5} \]  
(5.12)

\[ F_6(x) = f_6(M\left(\frac{5(x-o_6)}{100}\right)) + F^*_6 \]  
(5.13)

Properties:

1. Multi-modal
2. Non-separable

Shifted and Rotated HGBat Function

\[ f_7 = \left| \left( \sum_{i=1}^{D} x_i^2 \right)^2 - \left( \sum_{i=1}^{D} x_i \right)^2 \right|^{0.25} + \frac{0.5 \sum_{i=1}^{D} x_i^2 + \sum_{i=1}^{D} x_i}{D + 0.5} \]  
(5.14)

\[ F_7(x) = f_7(M\left(\frac{5(x-o_7)}{100}\right)) + F^*_7 \]  
(5.15)

Properties:

1. Multi-modal
2. Non-separable
Shifted and Rotated Expanded Griewank’s plus Rosenbrock’s Function

\[ f_8(x) = f_{11}(f_{10}(x_{x_1,x_2})) + f_{11}(f_{10}(x_{x_2,x_3})) + \cdots + f_{11}(f_{10}(x_{x_{D-1},x_D})) + f_{11}(f_{10}(x_{x_D,x_1})) \]  

(5.16)

\[ F_8(x) = f_8(M(\frac{5(x - o_8)}{100}) + 1) + F_8^* \]  

(5.17)

Properties:

1. Multi-modal

2. Non-separable

Shifted and Rotated Expanded Scaffer’s F6 Function

\[ g(x, y) = 0.5 + \frac{(\sin^2(\sqrt{x^2 + y^2}) - 0.5)}{(1 + 0.001(x^2 + y^2))^2} \]  

(5.18)

\[ f_9(x) = g(x_1, x_2) + g(x_2, x_3) + \cdots + g(x_{D-1}, x_D) + g(x_D, x_1) \]  

(5.19)

\[ F_9(x) = f_9(M(x - o_9) + 1) + F_9^* \]  

(5.20)

Properties:

1. Multi-modal

2. Non-separable

Hybrid Functions

Hybrid Function 1

This function is a hybrid of three functions: Modified Schwefel’s function, Rastrigin’s function, and High Conditioned Elliptic function.

\[ F_{10}(x) = 0.3 \times F_4(x) + 0.3 \times F_{12}(x) + 0.4 \times F_{13}(x) \]  

(5.21)
Hybrid Function 2

This function is a hybrid of 4 functions: Griewank’s function, Weierstrass function, Rosenbrock’s function, and Scaffer’s F6 function.

\[ F_{11}(x) = 0.2 \times F_{11}(x) + 0.2 \times F_3(x) + 0.3 \times F_{10}(x) + 0.3 \times F_9(x) \]  \hspace{1cm} (5.22)

Hybrid Function 3

This function is a hybrid of 5 functions: Katsuura function, HappyCat function, Expanded Griewank’s plus Rosenbrock’s function, Modified Schwefel’s function, and Ackley’s function.

\[ F_{12}(x) = 0.1 \times F_5(x) + 0.2 \times F_6(x) + 0.2 \times F_8(x) + 0.2 \times F_4(x) + 0.3 \times F_{14}(x) \]  \hspace{1cm} (5.23)

Composite Functions

The general format of composite function is as follows:

\[ F(x) = \sum_{i=1}^{N} \{ \omega_i \times [\lambda_i g_i(x) + bias_i] \} + f^* \]  \hspace{1cm} (5.24)

\( F(x) \): composition function

\( g_i(x) \): \( i^{th} \) basic function used to construct the composition function

\( N \): number of basic functions

\( \omega_i \): new shifted optimum position for each \( g_i(x) \), define the global and local optima’s position.

\( bias_i \): defines which optimum is global optimum.

\( \lambda_i \): used to control each \( g_i(x) \)’s coverage range, a small \( \sigma_i \) give a narrow range for that \( g_i(x) \)

\( \lambda_i \): used to control each \( g_i(x) \)’s height
$w_i$: weight value for each $g_i(x)$, calculated as follows:

$$w_i = \frac{1}{\sqrt{\sum_{j=1}^{D}(x_j-o_{ij})^2}} \exp\left(-\frac{\sum_{j=1}^{D}(x_j-o_{ij})^2}{2D\sigma_i^2}\right)$$ (5.25)

Now, the value of $\omega_i$ weight is calculated as:

$$\omega_i = \frac{w_i}{\sum_{i=1}^{n} w_i}$$ (5.26)

**Composition Function 1**

Five types of basic functions are combined to construct this function:

N = 5, $\sigma = [10, 20, 30, 40, 50]$, $\lambda = [1, 1e-6, 1e-26, 1e-6, 1e-6]$, bias = [0, 100, 200, 300, 400]

g_1: Rotated Rosenbrock’s Function $f_{10}$

g_2: High Conditioned Elliptic Function $f_{13}$

g_3: Rotated Bent Cigar Function $f_1$

g_4: Rotated Discus Function $f_2$

g_5: High Conditioned Elliptic Function $f_{13}$

Properties:

1. Multi-modal
2. Non-separable
3. Asymmetrical
4. Different properties around different local optima

**Composition Function 2**

Three types of basic functions are combined to construct this function:

N = 3, $\sigma = [10, 30, 50]$, $\lambda = [0.25, 1, 1e-7]$, bias = [0, 100, 200]
\( g_1 \): Rotated Schwefel’s function \( f_4 \)  
\( g_2 \): Rotated Rastrigin’s function \( f_{12} \)  
\( g_3 \): Rotated High Conditioned Elliptic function \( f_{13} \)

Properties:

1. Multi-modal  
2. Non-separable  
3. Asymmetrical  
4. Different properties around different local optima

**Composition Function 3**

Five types of basic functions are combined to construct this function:

\[ N = 5, \; \sigma = [10, 10, 10, 20, 20], \; \lambda = [10, 10, 2.5, 25, 1e-6], \; \text{bias} = [0, 100, 200, 300, 400] \]

\( g_1 \): Rotated HGBat Function \( f_7 \)  
\( g_2 \): Rotated Rastrigin’s Function \( f_{12} \)  
\( g_3 \): Rotated Schwefel’s Function \( f_4 \)  
\( g_4 \): Rotated Weierstrass Function \( f_3 \)  
\( g_5 \): Rotated High Conditioned Elliptic Function \( f_{13} \)

Properties:

1. Multi-modal  
2. Non-separable  
3. Asymmetrical  
4. Different properties around different local optima
Parameters Settings

We used the same initial values for the parameters as presented by [Ali et al., 2016]:

- Population Size: 90
- Number of tribes: 10
- The window-size for applying the social influence with restructuring (Wsize): 20
- The proportion of the best agents to be sent to the belief space (Pa): 0.25
- The number of elites in each tribe (nelite): 2
- The threshold trigger for restructuring (Mthresh): 50
- Tie-breaking rule (TieR): MFU
- The maximum number of function evaluations (MaxFES): 150000
- The social factor (Sf) is an integer value variable that takes a value between 0 and 3. Note that these figures correspond to topologies, lbest, von-Neumann,n-star-bus, and gbest.

Here, we use MaxFES as a stopping criterion. There are 20 independent runs for each function. And each function is tested for 10 and 30 number of dimensions.
Chapter 6

Evaluation, Analysis and Comparisons

In this chapter, we present a detailed comparison of our two approaches: Irregular neighborhood restructuring (ISFCA) and Confidence-based normative knowledge source (CSFCA) with other methods. We chose the standard social fabric algorithm by [Ali et al., 2016] and Tribe-PSO by [Chen et al., 2006] for the purpose of comparison, as both of them utilize social structures and a tribal approach.

We compare the approaches on each function with 10 and 30 dimensions. For each function, an overall comparison is presented regarding mean, median, best, and standard deviation (StdDev). Then, average fitness values of 10 experiments with different random generator settings are presented.

Function 1: Bent Cigar Function

In table 6.1 and figure 6.1, we can see that both of our approaches (ISFCA and CSFCA) and TPSO outperform the standard SFCA impressively with 98% and 55% for optimization of 10 dimensions. In the case of 30-dimension optimization, ISFCA and CSFCA perform with 60% and 42% improvement respectively.

Function 2: Discus Function

As we can see in the table 6.3 and 6.3, for 10-dimension optimization, ISFCA and CSFCA improve by 99% and 42% on the function 2. As explained in table 6.4 and 6.4, they outperform the standard algorithm by 99% and 95% for 30-dimension optimization.

Summary of Results

In this chapter, we presented an extensive comparison of our proposed approaches with the standard social fabric algorithm [Ali et al., 2016] and Tribe-PSO [Chen et al., 2006]. We chose these algorithms because both of them utilize multi-population and tribal strategies to improve the level of diversity in evolutionary algorithms.

As we can in the tables and figures for the functions 1, 2, 8, 10, and 12, the new neighborhood restructuring strategy and the confidence-based normative ranges generated more than 50% improvement. It seems the proposed methods succeeded to help the individuals to avoid stagnation and local optima.

For the functions 4, 7, 11, 13, 14, and 15 the new approaches improve the performance with a lower percentage between 10% and 20%. Although, for the remaining functions the generated improvement is trivial. We hypothesize that it occurred because of the high-level complexity of the benchmark functions we used. In the standard implementation of the IEEE-CEC2015 library, the functions are twisted and rotated to make it hard for optimization algorithms to get rid of local optima [Chen et al.,...
2014]. Also, as it is stated by above mentioned the No-Free Lunch Theorem, it is not expected for an optimization algorithm to work well on all of the possible functions [Wolpert and Macready, 1997].
Chapter 7

Conclusion and Future Work

Conclusion

In this thesis, two novel strategies were introduced to improve the robustness of CAs in both population and belief spaces. In the first strategy, a new neighborhood restructuring strategy is employed which aims at individuals with irregular and heterogeneous neighborhood structures. There is no centralized coordinator to control the topology of a population because the individuals are responsible for inspecting and modifying their neighborhood in a self-organized manner. Increasing the level of self-organization and autonomy is a key approach to improving robustness in a complex system. In the second strategy, the standard implementation of normative ranges in the belief space was replaced by the confidence intervals inspired from Inferential Statistics. The new knowledge source shows a more robust search behavior to fluctuations in the input data. Now, the size of normative ranges does not change dramatically with any temporal fluctuations.

For the new neighborhood restructuring, a fundamental assumption is that the individuals have to handle their interactions within a social network (fabric) infrastructure. Here, the social fabric is modeled using a dynamic graph which the neigh-
neighborhood size of the nodes (individuals) changes with time. This assumption implies another assumption that the interactions between agents occur locally. It means that the amount of influence which the individuals can receive from the other members is limited by their neighborhood size. In fact, this assumption is a key to avoiding immature convergence. As the agents are responsible for inspecting and modifying their neighborhood, the only limitation which we surmise when the size of a population increase, is the performance issues. Since the population is divided into some independent subpopulations (tribes), each tribe could be run in a separate thread. Running all the population in a single thread may pose a heavy burden on performance.

The second approach, confidence-based normative knowledge source, does not assume anything more than its standard version. It is entirely independent of the strategies deployed in the population space. In fact, the confidence-based approach could be utilized in the same framework as well as the standard method. So, it does not pose any additional limitations to the algorithm.

Future Work and Applications

The performance of both proposed approaches is assessed through a test-suite of 15 multi-modal and hybrid functions from IEEE-CEC2015. Both methods are compared to the original version of the social fabric based CA [Ali et al., 2016]. The results show improvement in most of the functions. In some of them, the results are quite promising.

We only tested our approaches against static functions, which means there is no change in the feedback from the environment. The improved robustness of the new methods makes them suitable to be utilized in dynamic problems like real-time applications where the algorithm needs to inspect and adapt itself to a changing environ-
ment continuously and as fast as possible [Che et al., 2010]. The new neighborhood restructuring method allows the individuals to develop relationships in promising parts of the search space autonomously. The deployed inspect and adapt strategy makes it easy for the agents to change their point of focus and restructure themselves to find new optimum points in a non-stable search space. Also, the new update scheme for the normative ranges in the belief space can be considered suitable for such applications since it avoids deviation with any temporal change in the input data pattern.

With the growing industrial demands for data analytics, evolutionary algorithms could be the source of inspiration for the solutions to address such problems. The self-organization aspect of EAs makes them scalable to be used for analyzing datasets with a high level of complexity. [Xiaodong et al., 2008], [Pizzuti, 2008], and [Sherkat et al., 2015] are the examples which show promising results in social network analysis. They used EA methods such as GA, CA, and PSO for community detection and link prediction applications. [Sousa et al., 2004] and [Otero et al., 2012] are the examples which proposed new approaches for data classification based on PSO and ACO. So, these research works have created a good background to use our proposed strategies for analytic applications.
BIBLIOGRAPHY

VITA AUCTORIS

Bahram Zaeri completed his Bachelor’s degree in Computer Science from the Islamic Azad University in Iran in the year 2008. Then, he started working as a software developer in Tehran, Iran for about 5 years. He has worked in numerous big and medium scale projects as both back-end and front-end developer with different languages such as Java, Javascript, C#, and etc. Also, he is interested in AI and specially Swarm Intelligence. He has published some papers and articles about Ant Colony Optimization (ACO) and its applications. He will complete his Master of Science in Computer Science in 2017 through the University of Windsor.
